Research article The genetic basis of human pigmentation. Over 120 genes have been identified in the mouse that affect coat and skin colour and the human homologues of these genes are known. Single nucleotide polymorphisms (SNPs) in a number of these genes have been associated with various human hair, skin and eye colour phenotypes and a number of these SNPs have been shown to have functional affects.

Abstract. Cancer is a genetic disease in which malignant cells have undergone mutations and epigenetic changes but maintain the transformed phenotype even when cultured or when injected into immunologically tolerant experimental animals (1,2). However, most of the genetic events in tumors are somatic (i.e., not hereditary), brought about environmentally or randomly, and the identified inherited ...

The genetic changes that potentially underlie human brain evolution span a wide range from single nucleotide substitutions to large-scale structural alterations of the genome. Similarly, the functional consequences of these genetic changes vary greatly, including protein-sequence alterations, cis-regulatory changes and even the emergence of new genes and the extinction of existing ones.
